

Packman with OOP

Console base game project

Learning Objective

Develop a console game using object oriented programming.

Let's start the pacman game with oop

. %%	3/		%%%%%%%%%%%%%%%%%%	%	%%%%
	% %	%	% %	%	%
	% %	%	% %	%	%
	%%%%%%%%%	%	%%%%%%%%%%%%%%%%%%%%%		%%%%.
	%	%		%	
	%%%%%%%%%%%%	%	9/0/0/0/0/0/0/0/0/0/0/0/0	%	%%%%.
	%		%	%	% .
	%		% %		% .
. %	% %%% % . %	. %	%	%	% .
. %	% %	%%%%%%%%%%%%%%%	% %	. %	
. %	% %	p %	%%%%%%	. %	
. %		%		% %	
. %	%%%%%%%%%%%%%%%	% %	0/	% %	%%%%%
				%	
. %	% %	%%%%%%%%%%%%%%%		% %	
. %	% %	%	%//////////////////////////////////////	% %	(*)
. %		%	6	% %	
. %	%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%	% %	/ \%%%%%%%%%%	The second second second	%%%%%
				%	

How we can represent this grid in terms of OOP?

	7676	%%%%	(%%%)	6%%	6%%								%%	6%%	%%?	6%)	18/18/	%	1%	١.			%%	%%	6

Requirements of the Pacman Game

Identify the classes for these instructions????

- Pacman game is a grid with different components.
- A grid consist of different cells.
- Each cells can contains Players, Enemies, Walls, Rewards (Bullets) or some time may be nothing.
- Also Cell display different static game objects such as Walls.
- You can think cell is smallest unit of a grid that player (Pacman) and enemies can use to navigate in any allowed direction.
- A Cell should contain the information about its adjacent cells.
- A Pacman is player who can move with the keys.

Draw the domain model diagram of your identified classes for pacman

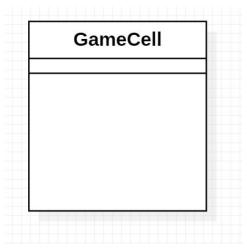

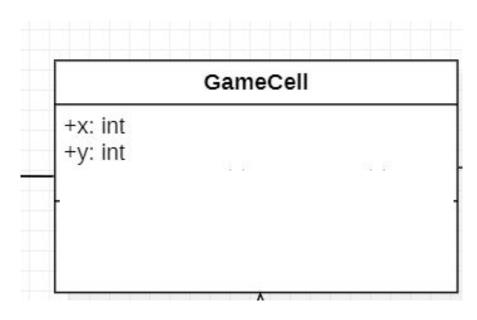

Let first creates set of classes that can represent the grid, cells and object within game

Let start with an atomic class and that is Cell

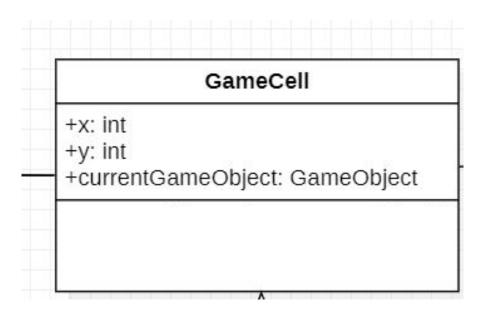

GameCell

Try to identify the attributes and functions of the class

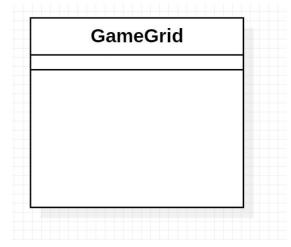

Do Cell need to have any other information?

Store the information of the GameObject that it is holding.

Now, what shall be the attributes of Grid Class; the class that will hold all the cells

Solution of the pacman with OOP

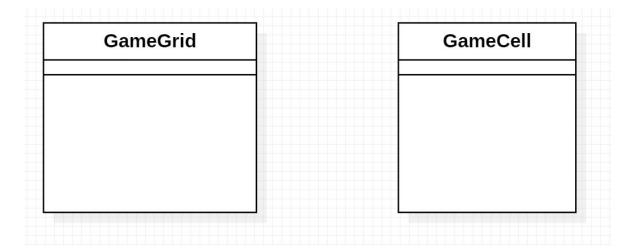

GameGrid

- +GameCells[][]: GameCell
- +Rows: int
- +Cols: int
- +GameGrid(string filename, int rows, int cols)
- -loadGrid(string filename)
- +getCell(int x, int y): GameCell

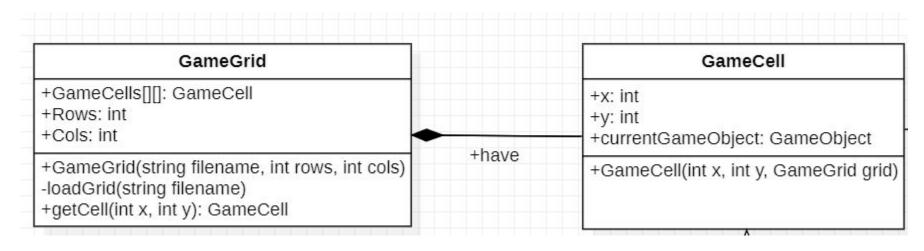

GameGrid contains the 2D Array of GameCells with two numbers of rows and columns,

A Constructor to initialize the variables a function to get any GameCell

Relationship among these two classes?

Solution of the pacman with OOP

Suppose game cell contains the GameObject reference and the X and Y variable that represents the Current GameCell position and a constructor to initialize the variables.

Question?

If we want to know from cell what are the adjacent cells of the current cell? How we can do that? What will be the function and which class will contain it?

Solution

There are two solutions for that.

Write that function inside the GameGrid class. If we do that we have to pass the cell to the GameGrid.

Other solution is that

We write the function inside the GameCell... In this case it need the GameGrid object.

If we see the second technique

If we write the function inside the GameCell... In this case it need the GameGrid object.

In this the GameGrid is composing the GameCell and GameCell is composing GameGrid.

Is that is ok?? Or its circular relationship between the classes?

GameCell

- +x: int
- +v: int
- +currentGameObject: GameObject
- +gameGrid: GameGrid
- +GameCell(int x, int y, GameGrid grid)
- +nextCell(GameDirection direction)

Important Instructions

- If a class contains the object of other class it does not mean its composition or aggregation everytime.
- Sometimes this is called message passing or association.
- Its is the same concepts but semantically it is different.

Important Instructions

Remember: GameGrid is containing the GameCell object this relationship is composition but GameCell contains the object of GameGrid its not the composition nor aggregation but general simple association.

We represent the association with simple line.

nextCell function with better approach

```
public GameCell nextCell(string direction)
{
```

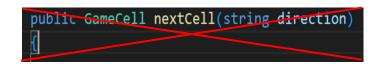

Here is cell direction is string type which will accept right, left, up or down as argument.

But we are developing Framework

When we are developing framework it mean someone else like other developers will use our code to develop their own games.

In that case if someone pass the left, right, up or down in different format or there is spelling mistake it will not work.

```
public GameCell nextCell(string direction)
{
```

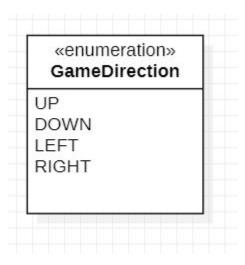

To avoid the following issue we use enumeration in C#

Enumeration is static class provided by the C# that we use to avoid such issues

What is enum in C#?

In C#, an enum (enumeration) is a distinct type that represents a set of named constants. It allows you to define a list of named values, making your code more readable and self-explanatory. Enums provide a way to group related constants together and use them in your code.

We represent enumeration in domain model with following format

Just like class we make a enum and define our named constants.

```
namespace PacMan.GameGL
     11 references
     enum GameDirection
          2 references
          Left,
          2 references
          Right,
          2 references
         Up,
          2 references
          Down
```

Before

```
public GameCell nextCell(string direction)
{
    nextCell("up");
```

After

```
2 references
public GameCell nextCell(GameDirection direction)
{
nextCell(GameDirection.Up);
```

The enum technique is more meaningful and error prone.

Before

```
public GameCell nextCell(string direction)
    nextCel
```

```
nextCell("up");
```

After

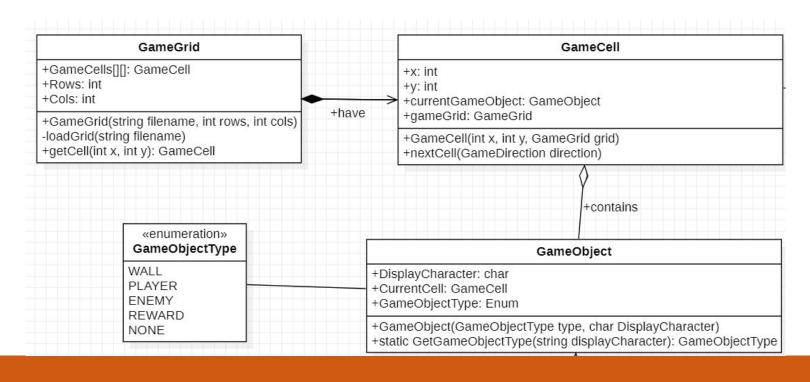

```
2 references
public GameCell nextCell(GameDirection direction)
{
```

```
nextCell(GameDirection.Up);
```

The enum technique is more meaningful and error prone.

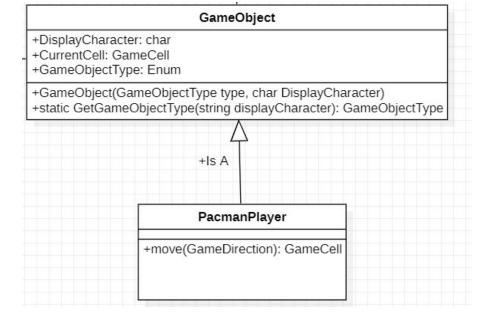

GameObject

GameObject will be the made of following attributes
Here the GameObjectType is enumeration

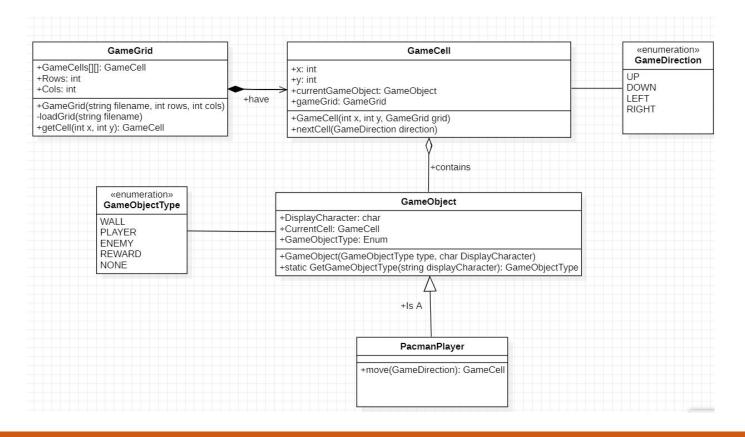

Pacman Class

Make pacman separate class and it will extends the GameObject

Complete Domain Model

Driver Program

Get the Program.cs code from google classroom and use our class diagram and make your game

Framework Task 01

Make the complete game with above discussed method
